COMP9020 19T1 Week 5 Graphs

- Textbook (R & W) Ch. 3, Sec. 3.2 Ch. 6, Sec. 6.1–6.5
- A. Aho & J. Ullman. Foundations of Computer Science in C,
 p. 522–526 (Ch. 9, Sec. 9.10)
- Problem set 5
- Supplementary Exercises Ch. 6 (R & W)
- Quiz 5 (due Monday week 6)
- Mid-term test Wednesday week 6

Mid-term Test

1 hour at your own time Wednesday, 27 March between 2:30pm and 3:35pm

Format:

- 7 questions, each worth 1, 2 or 3 between 2 and 5 marks, maximum marks: 20 15
- ullet mix of multiple choice (with =1 or ≥ 1 correct answers), open answer

The test will be manually marked, unlike the quizzes.

Practice test with sample solutions available but will not be marked.

Mid-term Test

If you

- ... are uncertain about how to interpret a question
- ... are unsure about how to answer a question
- ... find a question too difficult
- ⇒ do answer to the best of your understanding
- \Rightarrow do focus on the questions that you find easier
- \Rightarrow do not agonise about a question or your answer after you've submitted

Graphs

Terminology (the most common; there are many variants):

(Undirected) Graph — pair (V, E) where

V – set of vertices

E – set of edges

Every edge $e \in E$ corresponds uniquely to the set (an unordered pair) $\{x_e, y_e\}$ of vertices $x_e, y_e \in V$.

A *directed* edge is called an *arc*; it corresponds to the ordered pair (x_a, y_a) . A **directed graph** consist of vertices and arcs.

NB

Edges $\{x, y\}$ and arcs (x, y) with x = y are called *loops*. We will only consider graphs without loops.

NB. Binary relations on finite sets correspond to directed graphs. Symmetric relations correspond to undirected graphs.

Graphs in Computer Science

Examples

- The WWW can be considered a massive graph where the nodes are web pages and arcs are hyperlinks.
- 2 The possible states of a program form a directed graph.
- 3 The map of the earth can be represented as an undirected graph where edges delineate countries.

NB

Applications of graphs in Computer Science are abundant, e.g.

- route planning in navigation systems, robotics
- optimisation, e.g. timetables, utilisation of network structures
- compilers using "graph colouring" to assign registers to program variables

Vertex Degrees

• Degree of a vertex

$$\deg(v) = |\{ w \in V : (v, w) \in E \}|$$

i.e., the number of edges attached to the vertex

- Regular graph all degrees are equal
- Degree sequence $D_0, D_1, D_2, ..., D_k$ of graph G = (V, E), where $D_i = \text{no.}$ of vertices of degree i

Question

What is $D_0 + D_1 + ... + D_k$?

- $\sum_{v \in V} \deg(v) = 2 \cdot e(G)$; thus the sum of vertex degrees is always even.
- There is an even number of vertices of odd degree (6.1.8)

Paths

• A path in a graph (V, E) is a sequence of edges that link up

$$v_0 \xrightarrow{\{v_0,v_1\}} v_1 \xrightarrow{\{v_1,v_2\}} \dots \xrightarrow{\{v_{n-1},v_n\}} v_n$$

where $e_i = \{v_{i-1}, v_i\} \in E$

- **length** of the path is the number of edges: *n* neither the vertices nor the edges have to be all different
- Subpath of length $r: (e_m, e_{m+1}, \dots, e_{m+r-1})$
- Path of length 0: single vertex v₀
- Connected graph each pair of vertices joined by a path
- Connected **component** of *G* a connected subgraph of *G* that is not contained in a larger connected subgraph of *G*

Examples

Exercise

 $\boxed{6.1.13(a)}$ Draw a connected, regular graph on four vertices, each of degree 2

6.1.13(b) Draw a connected, regular graph on four vertices, each of degree 3

 $\boxed{6.1.13(c)}$ Draw a connected, regular graph on five vertices, each of degree 3

6.1.14(a) Graph with 3 vertices and 3 edges

6.1.14(b) Two graphs each with 4 vertices and 4 edges

Examples

Exercise

6.1.13 Connected, regular graphs on four vertices

none (c)

 $\boxed{6.1.14}$ Graphs with 3 vertices and 3 edges must have a *cycle*

NB

We use the notation

v(G) = |V| for the no. of vertices of graph G = (V, E)

e(G) = |E| for the no. of edges of graph G = (V, E)

Exercise

6.1.20(a) Graph with e(G) = 21 edges has a degree sequence $D_0 = 0, D_1 = 7, D_2 = 3, D_3 = 7, D_4 = ?$

Find v(G)!

6.1.20(b) How would your answer change, if at all, when $D_0 = 6$?

10

Exercise

6.1.20(a) Graph with e(G) = 21 edges has a degree sequence $D_0 = 0, D_1 = 7, D_2 = 3, D_3 = 7, D_4 = ?$

Find v(G)

 $\sum_{v} \deg(v) = 2|E|; \text{ here}$ $7 \cdot 1 + 3 \cdot 2 + 7 \cdot 3 + x \cdot 4 = 2 \cdot 21 \text{ giving } x = 2, \text{ thus}$ $v(G) = \sum_{v} D_{i} = 19.$

6.1.20(b) How would your answer change, if at all, when $D_0 = 6$? No change to D_4 ; v(G) = 25.

Cycles

Recall paths $v_0 \xrightarrow{e_1} v_1 \xrightarrow{e_2} \dots \xrightarrow{e_n} v_n$

- simple path $e_i \neq e_i$ for all edges of the path $(i \neq j)$
- closed path $v_0 = v_n$
- cycle closed path, all other v_i pairwise distinct and $\neq v_0$
- acyclic path $v_i \neq v_j$ for all vertices in the path $(i \neq j)$

NB

- $C_n = (e_1, \dots, e_n)$ is a cycle *iff* removing *any* single edge leaves an acyclic path. (Show that the 'any' condition is needed!)
- ② C is a cycle if it has the same number of edges and vertices and no proper subpath has this property. (Show that the 'subpath' condition is needed, i.e., there are graphs G that are **not** cycles and $|E_G| = |V_G|$; every such G must contain a cycle!)

Trees

- Acyclic graph graph that doesn't contain any cycle
- Tree connected acyclic graph
- A graph is acyclic iff it is a forest (collection of unconnected trees)

NB

Graph G is a tree

- \Leftrightarrow G is acyclic and $|V_G| = |E_G| + 1$. (Show how this implies that the graph is connected!)
- ⇔ there is exactly one simple path between any two vertices.
- \Leftrightarrow G is connected, but becomes disconnected if any single edge is removed.
- \Leftrightarrow G is acyclic, but has a cycle if any single edge on already existing vertices is added.

Exercise

6.7.3 (supp) Tree with *n* vertices, $n \ge 3$.

Always true, false or could be either?

- (a) $e(T) \stackrel{!}{=} n$
- (b) at least one vertex of deg 2
- (c) at least two v_1, v_2 s.t. $deg(v_1) = deg(v_2)$

Exercise

13

|6.7.3 (supp)| Tree with n vertices, $n \geq 3$.

Always true, false or could be either?

- (a) $e(T) \stackrel{?}{=} n$ False
- (b) at least one vertex of deg 2 Could be either
- (c) at least two v_1, v_2 s.t. $deg(v_1)=deg(v_2)$ True

NB

A tree with one vertex designated as *root* is called a **rooted tree**. It imposes an ordering on the edges: 'away' from the root — from parent nodes to children. This defines a level number of a node as its distance (= path length) from the root.

The *height* of a rooted tree is the largest level number of a vertex.

Another very common notion in Computer Science is that of a DAG — a directed, acyclic graph.

Graph Isomorphisms

 $\iota: G \longrightarrow H$ is a graph isomorphism if

- (i) $\iota: V_G \longrightarrow V_H$ is 1–1 and onto (a so-called *bijection*)
- (ii) $\{x,y\} \in E_G$ iff $\{\iota(x),\iota(y)\} \in E_H$

Two graphs are called *isomorphic* if there exists (at least one) isomorphism between them.

Graph Isomorphisms

 $\iota: G \longrightarrow H$ is a graph isomorphism if

- (i) $\iota: V_G \longrightarrow V_H$ is 1–1 and onto (a so-called *bijection*)
- (ii) $\{x,y\} \in E_G \text{ iff } \{\iota(x),\iota(y)\} \in E_H$

Two graphs are called *isomorphic* if there exists (at least one) isomorphism between them.

Example

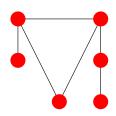

All nonisomorphic trees on 2, 3, 4 and 5 vertices.

Automorphisms and Asymmetric Graphs

An isomorphism from a graph to itself is called *automorphism*. Every graph has at least the trivial automorphism (trivial means: $\iota(v) = v$ for all $v \in V_G$)

Graphs with no non-trivial automorphisms are called *asymmetric*. The smallest non-trivial asymmetric graphs have 6 vertices.

(Can you find another one with 6 nodes? There are seven more.)

Edge Traversal

Definition

- Euler path path containing every edge exactly once
- Euler circuit closed Euler path

Characterisations

- G (connected) has an Euler circuit iff deg(v) is even for all $v \in V$.
- G (connected) has an Euler path iff either it has an Euler circuit (above) or it has exactly two vertices of odd degree.

NB

- These characterisations apply to graphs with loops as well
- For directed graphs the condition for existence of an Euler circuit is indeg(v) = outdeg(v) for all $v \in V$

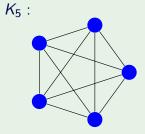

Special Graphs

- Complete graph K_n n vertices, all pairwise connected, $\frac{n(n-1)}{2}$ edges.
- Complete bipartite graph K_{m,n}
 Has m + n vertices, partitioned into two (disjoint) sets, one of n, the other of m vertices.
 All vertices from different parts are connected; vertices from the same part are disconnected. No. of edges is m · n.
- Complete k-partite graph $K_{m_1,...,m_k}$ Has $m_1+...+m_k$ vertices, partitioned into k disjoint sets, respectively of $m_1,m_2,...$ vertices. All vertices from different sets are connected; vertices from the same set are disconnected. No. of edges is $\sum_{i < j} m_i m_j = \frac{1}{2} \sum_{i \neq j} m_i m_j$
 - These graphs generalise the complete graphs $K_n = K_{\underbrace{1, \ldots, 1}}$

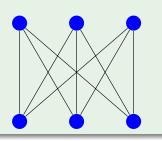

17

◆ロ ト ◆ 部 ト ◆ 恵 ト ◆ 恵 ・ 釣 へ ②

Example

 $K_{3,3}$:

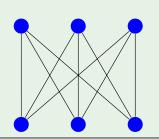

Exercise

6.2.14 Which complete graphs K_n have an Euler circuit? When do bipartite, 3-partite complete graphs have an Euler circuit?

Example

 $K_{3,3}$:

Exercise

|6.2.14| Which complete graphs K_n have an Euler circuit? When do bipartite, 3-partite complete graphs have an Euler circuit?

 K_n has an Euler circuit for n odd

 $K_{m,n}$ — when both m and n are even

 $K_{p,q,r}$ — when p+q,p+r,q+r are all even, ie. when p,q,r are all even or all odd

21

Vertex Traversal

Definition

- Hamiltonian path visits every vertex of graph exactly once
- Hamiltonian circuit visits every vertex exactly once except the last one, which duplicates the first

NB

Finding such a circuit, or proving it does not exist, is a difficult problem — the worst case is NP-complete.

Examples (when the circuit exists)

- All five regular polyhedra (verify!)
- *n*-cube; Hamiltonian circuit = *Gray code*
- K_m for all $m \ge 3$; $K_{m,n}$ iff m = n and $m, n \ge 2$
- Knight's tour on a chessboard (incl. rectangular boards)

Exercise

|6.5.5(a)| How many Hamiltonian circuits does $K_{n,n}$ have?

Exercise

6.5.5(a) How many Hamiltonian circuits does $K_{n,n}$ have? Let $V = V_1 \cup V_2$

- start at any vertex in V_1
- ullet go to any vertex in V_2
- ullet go to any *new* vertex in V_1
-

There are n! ways to order each part and two ways to choose the 'first' part, implying $c = 2(n!)^2$ circuits.

Given a graph it is nontrivial to verify that there is no Hamiltonian circuit: there is nothing obvious to specify that could assure us about this property.

In contrast, if a circuit is given, it is immediate to verify that it is a Hamiltonian circuit.

These situations demonstrate the often enormous discrepancy in difficulty of 'proving' versus (simply) 'checking'.

4□ > 4□ > 4□ > 4□ > 4□ > 4□

25

Colouring

Informally: assigning a "colour" to each vertex (e.g. a node in an electric or transportation network) so that the vertices connected by an edge have different colours.

Formally: A mapping $c: V \longrightarrow [1 ... n]$ such that for every $e = \{v, w\} \in E$

$$c(v) \neq c(w)$$

The minimum n sufficient to effect such a mapping is called the **chromatic number** of a graph G = (E, V) and is denoted $\chi(G)$.

NB

This notion is extremely important in operations research, esp. in scheduling.

There is a dual notion of 'edge colouring' — two edges that share a vertex need to have different colours. Curiously enough, it is much less useful in practice.

Properties of the Chromatic Number

- $\chi(K_n) = n$
- If G has n vertices and $\chi(G) = n$ then $G = K_n$

Proof.

Suppose that G is 'missing' the edge $\{v,w\}$, as compared with K_n . Colour all vertices, except w, using n-1 colours. Then assign to w the same colour as that of v.

- If $\chi(G) = 1$ then G is totally disconnected: it has 0 edges.
- If $\chi(G) = 2$ then G is bipartite.
- For any tree $\chi(T) = 2$.
- For any cycle C_n its chromatic number depends on the parity of n for n even $\chi(C_n) = 2$, while for n odd $\chi(C_n) = 3$.

Cliques

Graph (V', E') subgraph of $(V, E) - V' \subseteq V$ and $E' \subseteq E$.

Definition

A **clique** in G is a *complete* subgraph of G. A clique of k nodes is called k-clique.

The size of the largest clique is called the *clique number* of the graph and denoted $\kappa(G)$.

Theorem

 $\chi(G) \geq \kappa(G)$.

Proof.

Every vertex of a clique requires a different colour, hence there must be at least $\kappa(G)$ colours.

However, this is the only restriction. For any given k there are graphs with $\kappa(G) = k$, while $\chi(G)$ can be arbitrarily large.

NB

This fact (and such graphs) are important in the analysis of parallel computation algorithms.

- $\kappa(K_n) = n$, $\kappa(K_{m,n}) = 2$, $\kappa(K_{m_1,...,m_r}) = r$.
- If $\kappa(G) = 1$ then G is totally disconnected.
- For a tree $\kappa(T) = 2$.
- For a cycle C_n $\kappa(C_3) = 3$, $\kappa(C_4) = \kappa(C_5) = \ldots = 2$

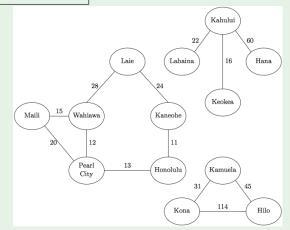

The difference between $\kappa(G)$ and $\chi(G)$ is apparent with just $\kappa(G) = 2$ — this does not imply that G is bipartite. For example, the cycle C_n for any odd n has $\chi(C_n) = 3$.

Exercise

29

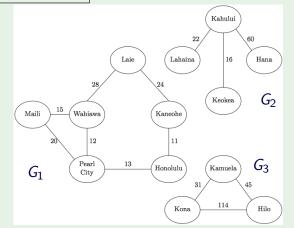

9.10.1 (Aho & Ullman)

 $\chi(G)$? $\kappa(G)$? A largest clique?

Exercise

9.10.1 (Aho & Ullman)

$$\chi(G_1) = \kappa(G_1) = 3; \quad \chi(G_2) = \kappa(G_2) = 2; \quad \chi(G_3) = \kappa(G_3) = 3$$

Exercise

9.10.3 (Aho & Ullman) Let G = (V, E) be an undirected graph. What inequalities must hold between

- the maximal deg(v) for $v \in V$
- χ(G)
- κ(G)

 $extit{max}_{v \in V} extit{deg}(v) + 1 \geq \chi(G) \geq \kappa(G)$

Exercise

9.10.3 (Aho & Ullman) Let G = (V, E) be an undirected graph. What inequalities must hold between

- the maximal deg(v) for $v \in V$
- $\chi(G)$
- κ(G)

 $max_{v \in V} deg(v) + 1 \ge \chi(G) \ge \kappa(G)$

4□ > 4□ > 4□ > 4□ > 4□ > 4□

34

Planar Graphs

Definition

33

A graph is **planar** if it can be embedded in a plane without its edges intersecting.

Theorem

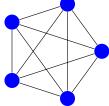

If the graph is planar it can be embedded in a plane (without self-intersections) so that all its edges are straight lines.

NB

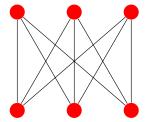

This notion and its related algorithms are extremely important to VLSI and visualising data.

Two minimal nonplanar graphs

 K_5 :

 $K_{3,3}$:

◆ロト ◆昼 ト ◆ 昼 ト ● ● 9 Q (~)

Exercise

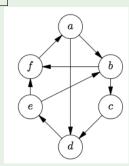

9.10.2 (Aho & Ullman)

Is (the undirected version of) this graph planar?

Exercise

9.10.2 (Aho & Ullman)

Is (the undirected version of) this graph planar? Yes

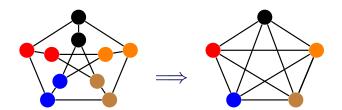

4□ > 4□ > 4□ > 4□ > 4□ > 4□ <

Theorem

37

If graph G contains, as a subgraph, a nonplanar graph, then G itself is nonplanar.

A *minor* of a graph is any graph obtained by repeatedly deleting vertices, deleting edges and merging *adjacent* vertices.

Theorem

A graph is nonplanar iff it contains K_5 or $K_{3,3}$ as a minor.

Theorem

 K_n for $n \geq 5$ is nonplanar.

Proof.

It contains K_5 : choose any five vertices in K_n and consider the subgraph they define.

Theorem

 $K_{m,n}$ is nonplanar when $m \ge 3$ and $n \ge 3$.

Proof.

They contain $K_{3,3}$ — choose any three vertices in each of two vertex parts and consider the subgraph they define.

Question

Are all $K_{m,1}$ planar?

Answer

Yes, they are trees of two levels — the root and m leaves

Question

Are all $K_{m,1}$ planar?

Answer

Yes, they are trees of two levels — the root and m leaves.

Question

Are all $K_{m,2}$ planar?

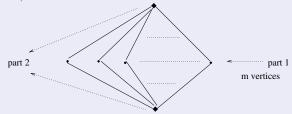

Question

Are all $K_{m,2}$ planar?

Answer

Yes; they can be represented by "glueing" together two such trees at the leaves.

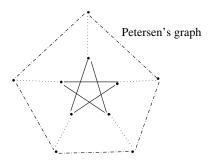

Sketching $K_{m,2}$:

Also, among the k-partite graphs, planar are $K_{2,2,2}$ and $K_{1,1,m}$. The latter can be depicted by drawing one extra edge in $K_{2,m}$, connecting the top and bottom vertices.

NB

Finding a 'basic' nonplanar obstruction is not always simple.

It contains both $K_{3,3}$ and K_5 as a minor (cf. Slide 39) while it does not directly contain either of them.

Summary

- Graphs, trees, vertex degree, connected graphs, connected components, paths, cycles C_n
- Graph isomorphisms, automorphisms
- Special graphs: complete K_n , complete bi-, k-partite K_{m_1,\ldots,m_k}
- Traversals
 - Euler paths and circuits (edge traversal)
 - Hamiltonian paths and circuits (vertex traversal)
- Graph properties: chromatic number $\chi(G)$, clique number $\kappa(G)$, planarity
